Understanding the Impact Factor

The impact factor is a widely recognized metric that quantifies the average number of citations received per paper published in a journal during the preceding two years. It serves as an indicator of a journal's academic influence and visibility. Calculated annually by Clarivate Analytics and published in the *Journal Citation Reports (JCR)*, the impact factor assists researchers in identifying reputable journals for publishing their work and assessing the quality of publications.

Calculation Methodology

The impact factor is calculated by dividing the number of citations in the current year to articles published in the previous two years by the total number of citable articles published in the same two years. For example, if a journal received 1,000 citations in 2023 to articles published in 2021 and 2022, and published 200 articles during those two years, its 2023 impact factor would be 5.0. This standardized approach allows consistent comparison across journals.

Limitations and Criticisms

While the impact factor is a useful metric, it has limitations. It does not measure the quality of individual articles and can be influenced by factors such as journal size, citation practices, and field-specific citation behaviors. Critics argue that overemphasis on impact factor may encourage citation manipulation and undervalue other forms of scholarly output.

frontiers in physiology impact factor: Climate, Ticks and Disease Pat Nuttall, 2021-11-26 This book brings together expert opinions from scientists to consider the evidence for climate change and its impacts on ticks and tick-borne infections. It considers what is meant by 'climate change', how effective climate models are in relation to ecosystems, and provides predictions for changes in climate at global, regional and local scales relevant for ticks and tick-borne infections. It examines changes to tick distribution and the evidence that climate change is responsible. The effect of climate on the physiology and behaviour of ticks is stressed, including potentially critical impacts on the tick microbiome. Given that the notoriety of ticks derives from pathogens they transmit, the book considers whether changes in climate affect vector capacity. Ticks transmit a remarkable range of micro- and macro-parasites many of which are pathogens of humans and domesticated animals.

The intimacy between a tick-borne agent and a tick vector means that any impacts of climate on a tick vector will impact tick-borne pathogens. Most obviously, such impacts will be apparent as changes in disease incidence and prevalence. The evidence that climate change is affecting diseases caused by tick-borne pathogens is considered, along with the potential to make robust predictions of future events.

frontiers in physiology impact factor: Renin-Angiotensin-Aldosterone System - Latest Trends Takaaki Senbonmatsu, Makoto Katoh, 2025-04-16 Renin-Angiotensin-Aldosterone System - Latest Trends consists of five chapters related to the renin-angiotensin-aldosterone system (RAAS). RAAS is a crucial hormonal system that regulates blood pressure, blood volume, and sodium (salt) balance in the body. When the kidneys detect abnormalities in hemodynamics, such as a drop in blood pressure or sodium concentration, renin is secreted, leading to the production of angiotensin II, which is a physiologically active substance. Angiotensin II causes cell proliferation, vasoconstriction, and sodium reabsorption through the angiotensin II type 1 receptor (AT1 receptor), helping maintain hemodynamic balance. Additionally, the AT1 receptor stimulates aldosterone secretion from the adrenal cortex. Aldosterone regulates sodium reabsorption and potassium excretion in the kidneys. Excessive activity of this system can lead to cardiovascular diseases. To address this, RAAS inhibitors such as angiotensin-converting enzyme inhibitors (ACEi), angiotensin II type 1 receptor blockers (ARB), direct renin inhibitors (DRI), and mineralocorticoid receptor antagonists (MRAs), also known as aldosterone blockers, are used to treat hypertension, heart failure, and arteriosclerosis. These therapies can be considered the 20th-century RAAS inhibitors. In the 21st century, the discovery of the (pro)renin receptor added a new dimension to the RAAS. The physiological activation mechanism following angiotensin II has also been elucidated. While research on the (pro)renin receptor as a RAAS-independent factor with organ-crossing functions and a potential therapeutic target continues, there is still no consensus on its role as part of the RAAS. Further research is needed to explore the physiological activation mechanism following angiotensin II. This book collects the latest research on RAAS, including studies on new indicators related to angiotensin-converting enzyme, and provides valuable information on its functions.
