Frequently Asked Questions

What is the difference between stress and strain in mechanical engineering?

Stress is the force applied per unit area on a material, while strain is the deformation or displacement that occurs due to the applied stress, expressed as a ratio of change in dimension to the original dimension.

Can you explain the concept of fatigue in materials?

Fatigue in materials refers to the weakening or failure of a material caused by repeatedly applied loads or cyclic stresses, even if the maximum stress is below the material's ultimate tensile strength.

What are the main types of gears and their applications?

The main types of gears include spur gears (used for parallel shafts), helical gears (smoother and quieter operation), bevel gears (used for intersecting shafts), and worm gears (used for large speed reductions and non-parallel shafts).

How do you calculate the factor of safety, and why is it important?

Factor of safety (FoS) is calculated as the ratio of the material's ultimate strength to the allowable or actual working stress. It is important to ensure that structures or components can withstand unexpected loads or conditions without failure.

What is the difference between a brittle and a ductile material?

Brittle materials fracture without significant deformation when stressed, while ductile materials undergo noticeable plastic deformation before fracture.

Explain the working principle of a four-stroke internal combustion engine.

A four-stroke engine works through four stages: intake (air-fuel mixture enters the cylinder), compression (mixture is compressed), power (ignition causes combustion pushing the piston), and exhaust (expelled gases exit the cylinder).

What is the significance of Reynolds number in fluid mechanics?

Reynolds number is a dimensionless quantity used to predict flow patterns in fluid dynamics, indicating whether the flow is laminar or turbulent based on the ratio of inertial forces to viscous forces.

Describe the difference between conduction, convection, and radiation heat transfer.

Conduction is heat transfer through direct contact of molecules, convection is heat transfer through fluid motion, and radiation is heat transfer through electromagnetic waves without requiring a medium.
